Change Log

Date	Change Description
2012-12-05	Initial release.

About this document

This document introduces the FortiAuthenticator RADIUS Accounting Proxy and it can be configured for use in a FortiGate or FortiMail environment. The document covers the configuration of the FortiAuthenticator only. Please see the FortiOS and FortiMail Admin Guides for details of how to configure those specific solutions.

Software versions

The configuration discussed in this document was tested on the following firmware versions:

- FortiAuthenticator 2.0 GA
- FortiOS 5.0 GA
- FortiMail 4.3

FortiAuthenticator RADIUS Accounting Proxy

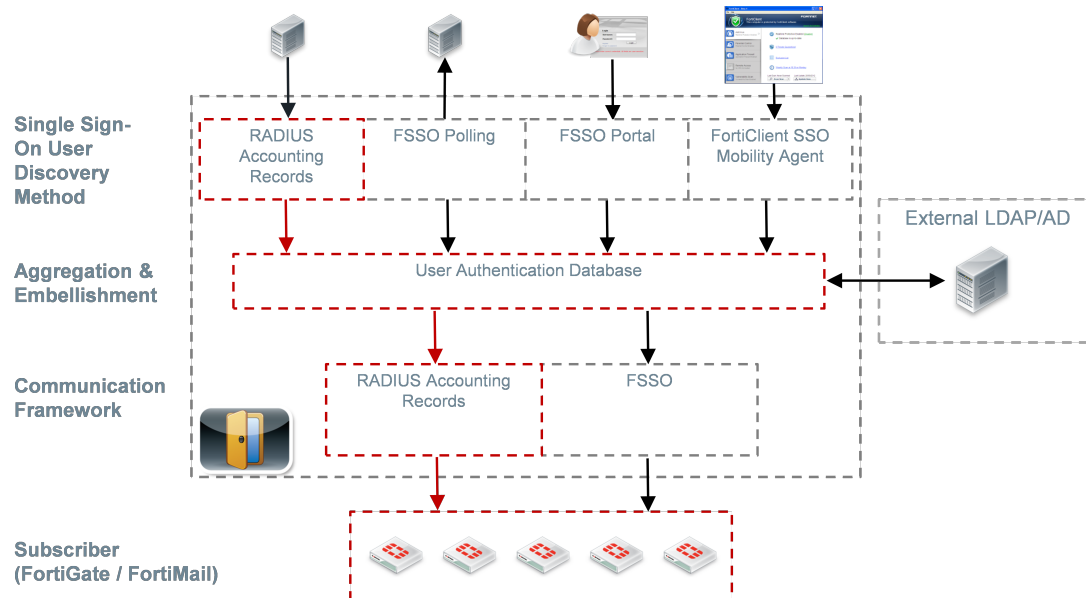

The FortiAuthenticator SSO Framework

In addition to explicit RADIUS and LDAP authentication, FortiAuthenticator supports the gathering of authentication state from external systems and the sharing with FortiGate (and in some cases FortiMail) for use in Identity Based Policies. Login events are gathered using multiple techniques and shared using one of two communications methods:

FSSO: Fortinet Single Sign-on

RSSO: RADIUS Single Sign-on using Attributes from RADIUS Accounting records.

Note that this document only covers the use of RADIUS Accounting Records for single sign-on. The use of FortiAuthenticator with FSSO authentication methods and communication is documented in the FortiAuthenticator FSSO Authentication Methods Guide <https://docs.fortinet.com/auth.html>

There are four layers within the FortiAuthenticator SSO framework:

Discovery
Methods:

Methods in which the user identity and their location (IP) are
discovered

Aggregation and Embellishment:	Collection of user identity and addition of any missing information (e.g. group)
Communication Framework:	Method by which the authentication information is communicated with the subscribing device
Subscriber:	Device that subscribes to the FortiAuthenticator FSSO feed

For the purpose of this document, only the flow shown in Red will be considered.

Introduction to RADIUS Accounting Proxy Authentication

RADIUS Accounting Proxy based authentication relies on the administrator configuring their existing RADIUS server to send Fortinet specific RADIUS AVP (Attribute Value Pairs) to each of the FortiGate?FortiMail devices requiring the login information. This is then used to identify and authenticate the user in future connections.

The drawback of this is that often, as the RADIUS Server is business critical, changes to the server are strictly limited. Additionally, in some cases, accounting records can only be sent to a single endpoint, not multiple endpoints as is required.

The FortiAuthenticator RADIUS Accounting Proxy functionality has been designed to overcome these limitations by proxying the RADIUS accounting records, modifying and replicating them to the multiple subscribing endpoints it in the process.

The following terminology is used throughout this document:

Source:	The source of the RADIUS Accounting records. This will be the existing RADIUS Server.
Destination:	The destination of the RADIUS Accounting records. This is one or more subscriber endpoints; FortiGate or FortiMail devices which will use the records for the purpose of identifying the users and their traffic.

Configuring the FortiAuthenticator

The RADIUS Accounting Proxy is configured via *SSO & Dynamic Policies* → *Accounting Proxy*. All other references to RADIUS, for example in the *SSO & Dynamic Policies* → *SSO* section are related to FSSO and should be avoided. See the FortiAuthenticator FSSO Authentication Methods Guide <http://docs.fortinet.com/d/fortiauthenticator-fsso-authentication-methods-configuration-guide-1> for more information on these methods.

1. Browse to *SSO & Dynamic Policies* > *Accounting Proxy* > *Sources* and configure an accounting source. This is usually the RADIUS server but the example below uses a laptop running NTRADPing for test purposes.

The screenshot shows the FortiAuthenticator web interface. The left sidebar is expanded to 'SSO & Dynamic Policies' > 'Accounting Proxy' > 'Sources'. The main area displays a table with one entry:

Name	Source Name/IP
Laptop	10.10.80.6

Below the table, it says '1 Radius accounting proxy source'.

2. Browse to *SSO & Dynamic Policies* > *Accounting Proxy* > *Destinations* and configure a list of accounting destinations. This is the list of FortiGate or FortiMail devices which will be using RADIUS Accounting for user identification and authentication.

The screenshot shows the FortiAuthenticator web interface. The left sidebar is expanded to 'SSO & Dynamic Policies' > 'Accounting Proxy' > 'Destinations'. The main area displays a table with two entries:

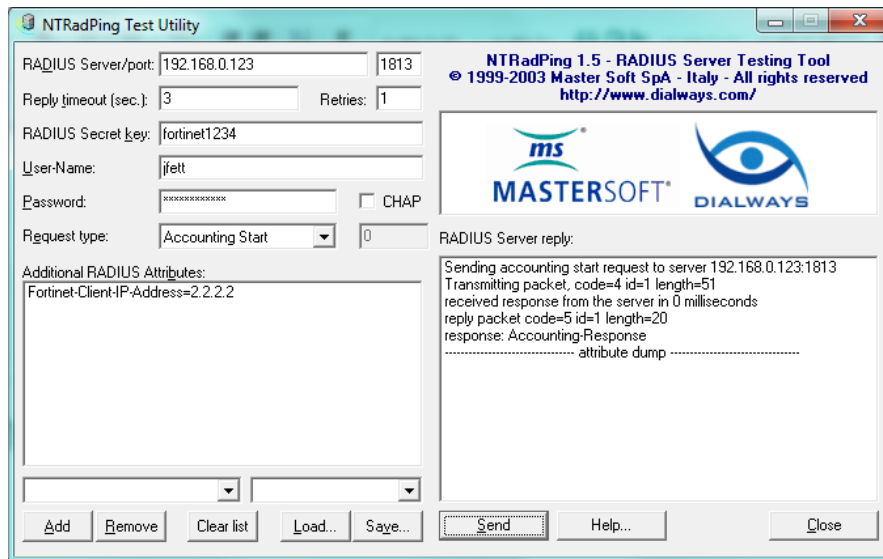

Name	Destination Name/IP	Source	Source -> Destination
192.168.0.2	192.168.0.2	Laptop (10.10.80.6)	10.10.80.6 -> 192.168.0.2
192.168.0.254	192.168.0.254	Laptop (10.10.80.6)	10.10.80.6 -> 192.168.0.254

Below the table, it says '2 Radius accounting proxy destinations'.

Sending RADIUS Accounting packets to the FortiAuthenticator from a RADIUS server will result in a login event being triggered on the FortiAuthenticator.

No authentication login state is maintained (unlike with the FSSO method) therefore the user will not appear in *Monitor* > *SSO* > *SSO Users*.

To verify the RADIUS packets are being “broadcast” to the destination endpoints, traffic sniffing can be employed.

```

Rule Sets

In situations where changes to the RADIUS infrastructure are restricted, it may not be possible to define the explicit attributes recommended by Fortinet and differing attributes may be required. FortiAuthenticator supports the mapping of existing attributes and addition of new attributes with dynamic values.

To create a new rule set:

- Browse to *SSO & Dynamic Policies > Accounting Proxy > Rule Sets*.

Attribute modification

- Select *Action: **Modify*** and select the source Attribute (*Attribute 1*) and Destination attribute (*Attribute 2*).

Attribute addition

1. Select *Action: **Add*** and select the Attribute you wish to create (*Attribute 1*).
2. Select the type of attribute you wish to create e.g a dynamic attribute such as UTM_Group or a static value.
3. Specify the LDAP server and query to pull the relevant values from LDAP.

Description:

Rules

Rule: #1 [✕](#)

Action:

Attribute: [\[Browse\]](#)

Attribute 2: [\[Browse\]](#)

Description: Rename attribute "Login-IP-Host" to "Fortinet-Client-IP-Address"

Rule: #2 [✕](#)

Action:

Attribute: [\[Browse\]](#)

Value type:

Attribute 2: [\[Browse\]](#)

Remote LDAP:

Description: Add attribute "Fortinet-Group-Name" containing "UTM profile groups" from group membership of "UTM_Group" attribute on remote LDAP server "WIN2008SVR (192.168.1.2:389)"

[+ Add another Rule](#)

Appendix A – Debugging RADIUS Accounting

To test RADIUS Accounting and verify correct configuration, it is most simple initially to test with desktop tools such as NTRADPing (provided by <http://www.mastersoft-group.com/download/>).

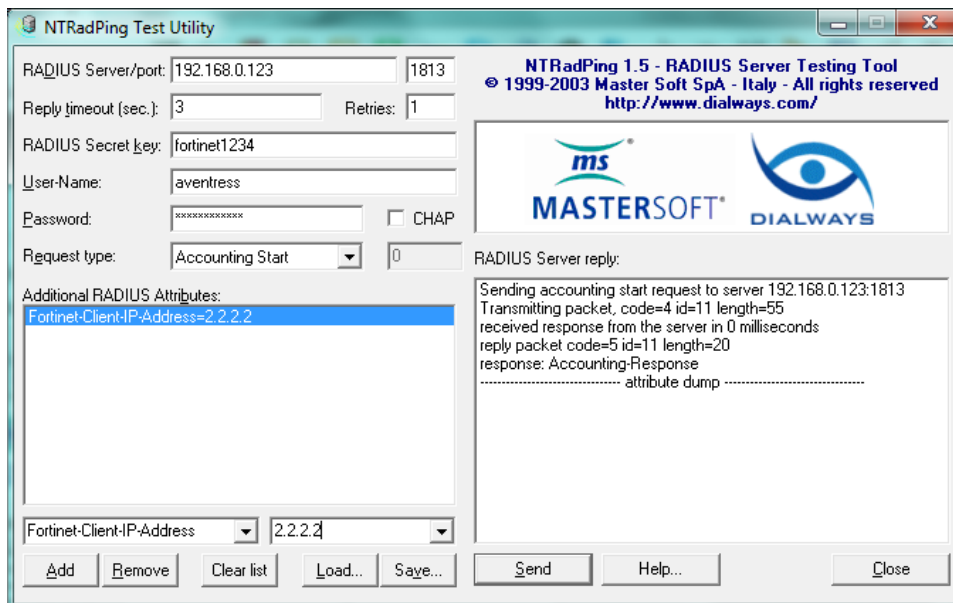

Once downloaded and installed, follow the instructions to install the Fortinet RADIUS Dictionary into the application.

To trigger a login into FSSO, the RADIUS packet must contain:

User-Name: <User name>

Fortinet-Client-IP-Address: <Client IP>

To replicate sending these attributes, configure the NTRADPing software as shown:

- Take care to ensure the RADIUS Port is changed to 1813 and the Request type is set to Accounting Start.
- It is not necessary to add an AVP for User-Name as it is specified in the explicit User-name field.
- If successful, FortiAuthenticator will acknowledge the receipt of the packet and the NTRADPing client will display this success with "Accounting-Response".
- If this is not successful, verify that UDP/1813 can pass to the FortiAuthenticator and that the RADIUS Secret Key is configured correctly on both sides.

Authentication may be successful but the user not found in LDAP (or LDAP is not configured correctly). In this case the login will be received but the record dropped due to lack of group info.
